Comparison of Keratometer Measurements to Simulated K's as Measured by Eyesys Corneal Analysis System, using Version 3.1 Software.

INTRODUCTION:

The uses of computerized video keratography (CVK) is expanding, for example in contact lens fitting, refractive surgery, keratoconus, etc. The standard way of measuring corneal curvature is by manuel keratometer measurements. The keratometer derives it's readings from a direct linear measurement taken between two pairs of points on a mire approximately 3.2 mm apart. The mires are reflected from the anterior surface of the cornea. In contrast, CVK uses a computer to analyze a series of eight concentric rings reflected off the cornea, giving 5,760 points over a nine mm diameter. This study is a comparison of the similarity between the EyeSys programs K readings to Manuel K readings.

METHODS:

Steepest and flattest corneal curvature methods were compared using a standard Marco Keratometer and the EyeSys Corneal Analysis System Unit, using Version 3.1 Software. A Nidek ARK 2000 Autorefractor was also used. Forty eyes were used in the study. The criteria for subject selection included a best corrected spectacle acuity of 20/20, a normal external and slit lamp examination, including no corneal irregularities and smooth K mires.

The data was gathered by two examiners to maintain a blind study. One examiner obtained corneal curvature measurements with the keratometer and another examiner obtained measurements from the EyeSys system. Refractive data was also collected for each eye.

RESULTS:

Table 1 shows the raw data for the diopters of toricity as measured with the standard keratometer and the EyeSys. Table 4 shows the difference between the delta K's of the two systems. Tables 2 and 3 show the refractive data collected for each eye.

SUMMARY:

Forty percent of the delta K's between the EyeSys and the keratometer varied within 0.10 Diopters from the mean value of the delta K from Table 4. Thirty two and a half percent of the delta K's between the two instruments varied within 0.11 to 0.20 Diopters from the mean value of the delta K from Table 4. Twenty percent varied within 0.21 to 0.30 Diopters, two and a half percent varied within 0.31 to 0.40 Diopters, and five percent varied within 0.41 to 1.00 Diopters from the mean value of the delta K in Table 4. Therefore, approximately 75% of the measurements taken varied up to 0.20 Diopters from the mean value of the delta K in Table 4. It can be stated that when measuring K readings from the EyeSys, and examiner can assume the measurements will be within 0.20 Diopters to the manuel keratometry readings.
